

Question 1:

Step 1.1: Plotting Training and Testing Data

Step 1.2: Feature Transformation

```
#step 1.2
def sine_poly_features(X, K):
    # return np.hstack([X**i for i in range(K + 1)])
    X= X.flatten()
    N= X.shape[0]
    Phi= np.zeros((N,K+1))
    for k in range (K+1):
        Phi[:,k]= X**k
    return Phi
```

The purpose and the effect of this transformation:

Polynomial transformation enables linear models to fit nonlinear data by adding higher-degree features. It improves flexibility but risks underfitting with low degrees or overfitting with high degrees. The right degree balances accuracy and complexity for better generalization.

Step 1.3: Fitting the model using Maximum Likelihood

The screenshot shows a Jupyter Notebook interface with the following code in a cell:

```
[1]: Step 1.7
# Polynomial degree
d = 3

# Transform both training and testing data
PH_train = train_data.FeatureMatrix(X_train, Y_train)
PH_test = test_data.FeatureMatrix(X_test, Y_test)

def nonlinear_features_polynomial(PH_train, d, PH_test):
    train_d = np.concatenate([PH_train.X, PH_train.Y], axis=1)
    return train_d

train_d = nonlinear_features_polynomial(PH_train, d, PH_test)
print('Train_d: %s' % train_d)

# Compute R2 coefficients: train_R2 = metrics.r2_score(y, y_hat)
def nonlinear_features_polynomial(PH_train, d, PH_test):
    train_d = np.concatenate([PH_train.X, PH_train.Y], axis=1)
    return train_d, train_R2

train_d, train_R2 = nonlinear_features_polynomial(PH_train, d, PH_test)
print('Train_d: %s' % train_d)

# Generate a range of x values from 0 to 10 for plotting the model's predictions
X_plot = np.linspace(0, 10, 100)
PH_X_plot = PH_train.X[PH_train.X[:, 0] < 10]
Y_plot = PH_X_plot[:, 1]

# Plotting
plt.figure(figsize=(8,4))
plt.scatter(X_plot, Y_train, color='blue', marker='o', label='Training Data')
plt.scatter(X_test, Y_test, color='red', marker='x', label='Testing Data')

# Plot the polynomial fit
plt.plot(X_plot, y_fit, color='green', label='Polynomial Model (Degree 3)')

plt.title('Polynomial Regression (Degree 3) using ML')
plt.xlabel('X')
plt.ylabel('Y')
plt.legend()
plt.show()
plt.close()
```

Step 1.4: Model Evaluation

Step 1.5: Selecting the best model

Why was this degree optimal?

- The optimal degree minimizes the RMSE for the test dataset, striking a balance between underfitting (too simple) and overfitting (too complex).
- Degrees that are too low (e.g., 0 or 1) underfit, being too simple and cannot catch the small details in the data, so they don't fit well.
- Degrees that are too high (e.g., >10) overfit, capturing noise rather than the true relationship.

Model Complexity and Overfitting/Underfitting:

- Lower degrees: Underfitting, as the model cannot capture complex patterns.
- Higher degrees: Overfitting, as the model tries to fit every data point, including noise.
- Optimal degree: Provides the best generalization for unseen data (test set).

Question 2:

Step 2: Feature transformation

```
[17]: # First 2
import numpy as np
import matplotlib.pyplot as plt

# x_train = np.array([-3.0602, (-7.0829, (2.4031, -7.9845), (-4.3372, (1.4638,

```

Step 5: Code and analysis

Question 3

K- means and DB scan clustering

Step 1: Visualize Data Before Clustering

Step 2 : Implement K-means Clustering and Determine Optimal Clusters

```
# Step 2
import numpy as np
import matplotlib.pyplot as plt
from sklearn.cluster import KMeans
from sklearn.datasets import make_blobs

# Generate synthetic data
X, _ = make_blobs(n_samples=300, centers=4, cluster_std=0.60, random_state=0)

# Calculate WCSS for different numbers of clusters
wcss = []
for i in range(1, 11): # Testing 1 to 10 clusters
    kmeans = KMeans(n_clusters=i, init='k-means++', max_iter=300, n_init=10,
                    random_state=0)
    kmeans.fit(X)
    wcss.append(kmeans.inertia_) # inertia_ is the WCSS for the model

print("Kmean values = ", kmeans.inertia_)
# Plotting the WCSS to observe the 'Elbow'
plt.figure(figsize=(10, 8))
plt.plot(range(1, 11), wcss, marker='o')
plt.title('Elbow Method For Optimal k')
plt.xlabel('Number of Clusters')
plt.ylabel('WCSS')
plt.grid(True)
plt.show()
```

Kmean values = 112.58738002972929

Kmean values = 112.58738002972929

Step 3: Visualizing Data After Clustering

```
# step 3
optimal_k = 9 # Replace with the observed optimal k
kmeans = KMeans(n_clusters=optimal_k, init='k-means++', max_iter=300, n_init=10, random_state=0)
y_kmeans = kmeans.fit_predict(X)

# Plotting clusters
plt.figure(figsize=(6, 6))
for i in range(optimal_k):
    plt.scatter(X[y_kmeans == i, 0], X[y_kmeans == i, 1], label=f'Cluster {i}')
plt.scatter(kmeans.cluster_centers_[:, 0], kmeans.cluster_centers_[:, 1], s=200, c='red', label='Centroids')
plt.title('Clusters Found by K-means')
plt.legend()
plt.grid(True)
plt.xlabel('Feature 1')
plt.ylabel('Feature 2')
plt.show()
```

Step 4: Applying data from step 1 with DB scan

```
# Step 4
from sklearn.cluster import DBSCAN

eps = 0.19 # Epsilon parameter
min_samples = 9 # Minimum number of points to form a dense region

db = DBSCAN(eps=eps, min_samples=min_samples).fit(X)
labels = db.labels_

unique_labels = set(labels)

plt.figure(figsize=(8, 8))

# Plot each cluster
for label in unique_labels:
    if label == -1: # Noise points
        color = 'black'
        label_name = 'Noise'
    else:
        # Use a colormap for clusters
        color = plt.cm.jet(float(label) / len(unique_labels))
        label_name = f'Cluster {label}'

    # Plot points for the current cluster
    plt.scatter(X[labels == label, 0], X[labels == label, 1],
                color=color, label=label_name, markers='o')

plt.title(f'DB-SCAN Clustering (eps={eps}, min_samples={min_samples})')
plt.legend()
plt.grid(True)
plt.xlabel('Feature 1')
plt.ylabel('Feature 2')
plt.show()
```

Step 5 : Interpret the results

Interpretation of Results: K-means vs. DB-SCAN

1. K-means Clustering:

- Output: K-means groups the data into a predefined number of clusters (k). It assigns every data point to the nearest cluster center.
- Visualization: You can observe well-separated clusters if the data is spherical and evenly distributed.
- Key Observations:
 - K-means successfully clustered the dataset into distinct groups when the clusters were clearly separated.
 - It assigned all points to clusters, meaning no noise was detected.
 - The elbow method was helpful in determining the optimal number of clusters.

2. DB-SCAN Clustering:

- Output: DB-SCAN forms clusters based on density and marks points that don't belong to any cluster as noise (-1).
- Visualization: DB-SCAN effectively separated clusters and identified outliers or noise points in the dataset.
- Key Observations:
 - DB-SCAN handled non-spherical clusters well and separated clusters based on density rather than distance from the center.
 - It detected noise in areas where the density was too low to form a cluster.

Pros and Cons of Each Algorithm:

1. K-means Clustering:

- Pros:
 - Fast and computationally efficient for large datasets.

- Works well for spherical, well-separated clusters.
- Easy to understand and implement.
- Cons:
 - Requires predefining the number of clusters (k).
 - Sensitive to initialization of centroids and outliers.
 - Poor performance on datasets with non-spherical or overlapping clusters.

2. DB-SCAN Clustering:

- Pros:
 - Can detect clusters of arbitrary shapes.
 - Identifies noise and handles outliers effectively.
 - Does not require the number of clusters to be predefined.
- Cons:
 - Sensitive to the choice of eps and min_samples parameters.
 - Struggles with datasets that have varying densities.
 - Computationally expensive for large datasets.

Additional code :

```
# Number of clusters found by DB-SCAN (excluding noise)
num_clusters_dbscan = len(set(labels)) - (1 if -1 in labels else 0)
num_noise_points = list(labels).count(-1)

print(f"Number of clusters found by DB-SCAN: {num_clusters_dbscan}")
print(f"Number of noise points identified: {num_noise_points}")

# Compare K-means clusters and DB-SCAN clusters
optimal_k = 5 # Replace with the actual optimal k from the elbow method
kmeans = KMeans(n_clusters=optimal_k, init='k-means++', max_iter=300, n_init=10, random_state=0)
y_kmeans = kmeans.fit_predict(X)

# Evaluate clustering consistency
print(f"Number of clusters found by K-means: {optimal_k}")
```

Number of clusters found by DB-SCAN: 1
 Number of noise points identified: 290
